Lehrstuhl für Algorithm Engineering (LS 11)

Fakultät für Informatik

TU Dortmund

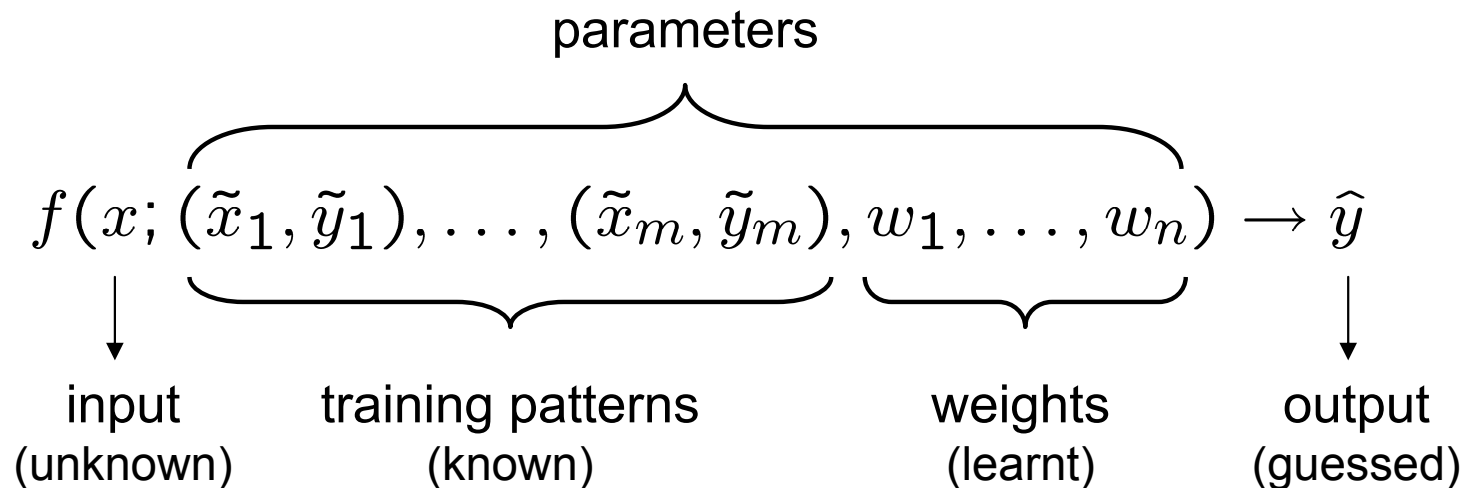

- Application Fields of ANNs
 - Classification
 - Prediction
 - Function Approximation
- Radial Basis Function Nets (RBF Nets)
 - Model
 - Training
- Recurrent MLP
 - Elman Nets
 - Jordan Nets

Classification

given: set of training patterns (input / output)

output = label
(e.g. class A, class B, ...)

\tilde{x}_i \tilde{y}_i

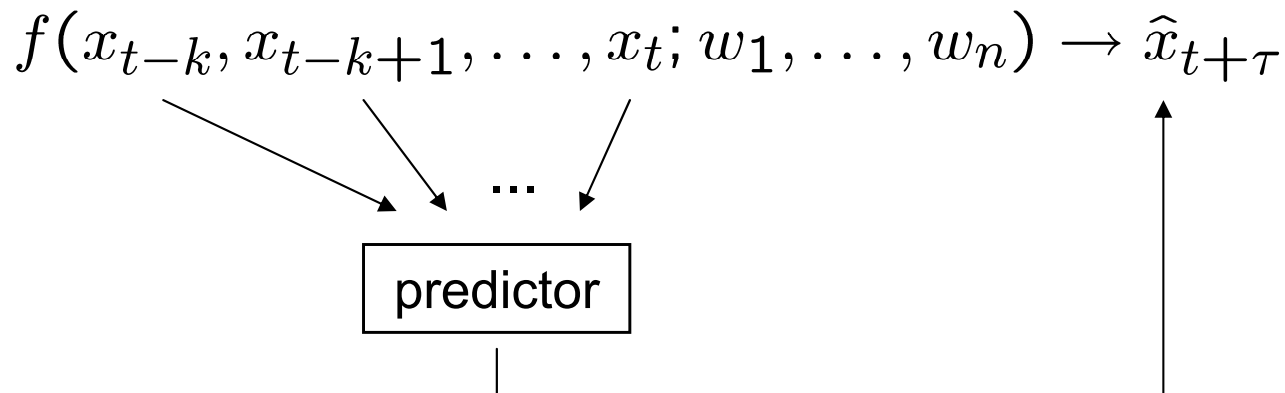

- phase I:**
train network
- phase II:**
apply network to unknown inputs for classification

Prediction of Time Series

time series x_1, x_2, x_3, \dots (e.g. temperatures, exchange rates, ...)

task: given a subset of historical data, predict the future

training patterns:

historical data where true output is known;

$$\text{error per pattern} = (\hat{x}_{t+\tau} - x_{t+\tau})^2$$

phase I:

train network

phase II:

apply network
to historical
inputs for
predicting
unknown
outputs

Function Approximation (the general case)

task: given training patterns (input / output), approximate unknown function

→ should give outputs close to true unknown function for arbitrary inputs

- values between training patterns are **interpolated**
- values outside convex hull of training patterns are **extrapolated**

x : input training pattern

o : input pattern where output to be interpolated

▲ : input pattern where output to be extrapolated

Definition:

A function $\phi : \mathbb{R}^n \rightarrow \mathbb{R}$ is termed **radial basis function** iff $\exists \varphi : \mathbb{R} \rightarrow \mathbb{R} : \forall \mathbf{x} \in \mathbb{R}^n : \phi(\mathbf{x}; \mathbf{c}) = \varphi(\|\mathbf{x} - \mathbf{c}\|)$. \square

Definition:

RBF **local** iff

$\varphi(r) \rightarrow 0$ as $r \rightarrow \infty$ \square

typically, $\|\mathbf{x}\|$ denotes Euclidean norm of vector \mathbf{x}

examples:

$$\varphi(r) = \exp\left(-\frac{r^2}{\sigma^2}\right)$$

Gaussian

unbounded

$$\varphi(r) = \frac{3}{4}(1 - r^2) \cdot 1_{\{r \leq 1\}}$$

Epanechnikov

bounded

$$\varphi(r) = \frac{\pi}{4} \cos\left(\frac{\pi}{2}r\right) \cdot 1_{\{r \leq 1\}}$$

Cosine

bounded

local

Definition:

A function $f: \mathbb{R}^n \rightarrow \mathbb{R}$ is termed **radial basis function net (RBF net)**

iff $f(x) = w_1 \varphi(\|x - c_1\|) + w_2 \varphi(\|x - c_2\|) + \dots + w_p \varphi(\|x - c_q\|)$ \square

- layered net
- 1st layer fully connected
- no weights in 1st layer
- activation functions differ

given : N training patterns (x_i, y_i) and q RBF neurons

find : weights w_1, \dots, w_q with minimal error

solution:

we know that $f(x_i) = y_i$ for $i = 1, \dots, N$ or equivalently

$$\sum_{k=1}^q w_k \cdot \underbrace{\varphi(\|x_i - c_k\|)}_{p_{ik}} = y_i$$

↓
↓
↓

unknown known value known value

$$\Rightarrow \sum_{k=1}^q w_k \cdot p_{ik} = y_i \quad \Rightarrow \text{N linear equations with q unknowns}$$

in matrix form: $P w = y$ with $P = (p_{ik})$ and $P: N \times q$, $y: N \times 1$, $w: q \times 1$,

case $N = q$: $w = P^{-1} y$ if P has full rank

case $N < q$: many solutions but of no practical relevance

case $N > q$: $w = P^+ y$ where P^+ is Moore-Penrose pseudo inverse

$P w = y$ | $\cdot P'$ from left hand side (P' is transpose of P)

$P'P w = P' y$ | $\cdot (P'P)^{-1}$ from left hand side

$(P'P)^{-1} P'P w = (P'P)^{-1} P' y$ | simplify

$\underbrace{(P'P)^{-1} P'P}_{\text{unit matrix}} w = \underbrace{(P'P)^{-1} P'}_{P^+} y$

complexity (naive)

$$w = (P'P)^{-1} P' y$$

remark: if N large then inaccuracies for $P'P$ likely

⇒ first analytic solution, then gradient descent starting from this solution

requires
differentiable
basis functions!

so far: tacitly assumed that RBF neurons are given
⇒ center c_k and radii σ considered given and known

how to choose c_k and σ ?

uniform covering

if training patterns
inhomogenously
distributed then first
cluster analysis

choose center of basis
function from each
cluster, use cluster size
for setting σ

advantages:

- additional training patterns → only local adjustment of weights
- optimal weights determinable in polynomial time
- regions not supported by RBF net can be identified by zero outputs

disadvantages:

- number of neurons increases exponentially with input dimension
- unable to extrapolate (since there are no centers and RBFs are local)

Jordan nets (1986)

- **context neuron:**
reads output from some neuron at step t and feeds value into net at step $t+1$

Jordan net =

MLP + context neuron
for each output,
context neurons fully
connected to input layer

Elman nets (1990)

Elman net =

MLP + context neuron for each neuron output of MLP,
context neurons fully connected to associated MLP layer

Training?

⇒ unfolding in time (“loop unrolling“)

- identical MLPs serially connected (finitely often)
- results in a large MLP with many hidden (inner) layers
- backpropagation may take a long time
- but reasonable if most recent past more important than layers far away

Why using backpropagation?

⇒ use *Evolutionary Algorithms* directly on recurrent MLP!

later!
